Bunched Implication Logic

- Motivated by separation logic used in pointer management in computer science.
- It is a substuctural logic and it combines an additive (Heyting) implication and a multiplicative (linear) implication.

A *residuated lattice*, is an algebra $\mathbf{L} = (L, \wedge, \vee, \cdot, \backslash, /, 1)$ such that

- (L, \wedge, \vee) is a lattice,
- $(L, \cdot, 1)$ is a monoid and
- for all $a, b, c \in L$,

$$ab \leq c \Leftrightarrow b \leq a \backslash c \Leftrightarrow a \leq c / b.$$

A *residuated lattice*, is an algebra $\mathbf{L} = (L, \wedge, \vee, \cdot, \backslash, /, 1)$ such that

- (L, \wedge, \vee) is a lattice,
- $(L, \cdot, 1)$ is a monoid and
- for all $a, b, c \in L$,

$$ab \leq c \Leftrightarrow b \leq a \backslash c \Leftrightarrow a \leq c / b.$$

If $xy = x \wedge y$ then \mathbf{L} is a *Brouwerian algebra* (Heyting algebra, if there is a bottom element). In this case we write $x \rightarrow y$ for $x \backslash y = y / x$.

A *residuated lattice*, is an algebra $\mathbf{L} = (L, \wedge, \vee, \cdot, \backslash, /, 1)$ such that

- (L, \wedge, \vee) is a lattice,
- $(L, \cdot, 1)$ is a monoid and
- for all $a, b, c \in L$,

$$ab \leq c \Leftrightarrow b \leq a \backslash c \Leftrightarrow a \leq c / b.$$

If $xy = x \wedge y$ then \mathbf{L} is a *Brouwerian algebra* (Heyting algebra, if there is a bottom element). In this case we write $x \rightarrow y$ for $x \backslash y = y / x$.

In every residuated lattice multiplication disctributes over join, so in a Heyting algebra the lattice is distributive.

A *residuated lattice*, is an algebra $\mathbf{L} = (L, \wedge, \vee, \cdot, \backslash, /, 1)$ such that

- (L, \wedge, \vee) is a lattice,
- $(L, \cdot, 1)$ is a monoid and
- for all $a, b, c \in L$,

$$ab \leq c \Leftrightarrow b \leq a \backslash c \Leftrightarrow a \leq c / b.$$

If $xy = x \wedge y$ then \mathbf{L} is a *Brouwerian algebra* (Heyting algebra, if there is a bottom element). In this case we write $x \rightarrow y$ for $x \backslash y = y / x$.

In every residuated lattice multiplication distributes over join, so in a Heyting algebra the lattice is distributive.

In general the lattice reduct need not be distributive, as in the lattice of ideals of a ring.

$$I \wedge J = I \cap J,$$

$$I \vee J = I + J, \text{ and}$$

IJ contains finite sums of products ij , as usual.

A *Generalized Bunched Implication algebra* (or *GBI algebra*)

$\mathbf{A} = (A, \wedge, \vee, \cdot, \backslash, /, 1, \rightarrow, \top)$ supports two residuated structures: a residuated lattice $(A, \wedge, \vee, \cdot, \backslash, /, 1)$ and a Brouwerian/Heyting algebra $(A, \wedge, \vee, \rightarrow, \top)$.

B. Jónsson and A. Tarski studied relation algebras inspired by the algebra of binary relations on a set. B. Jónsson further studied residuated structures with C. Tsinakis (Boolean monoids). Our interest with GBI algebras partly stems from these contributions.

B. Jónsson and A. Tarski studied relation algebras inspired by the algebra of binary relations on a set. B. Jónsson further studied residuated structures with C. Tsirikas (Boolean monoids). Our interest with GBI algebras partly stems from these contributions.

Given a set P for binary relations $R, S \in \mathcal{P}(P \times P)$, we define

- $R \wedge S = R \cap S$
- $R \vee S = R \cup S$
- $R \cdot S = R \circ S$ (relational composition)
- $R \rightarrow S = R^c \cup S = (R \cap S^c)^c$
- $R \backslash S = (R^\cup \circ S^c)^c$ (where R^\cup is the converse of R)
- $S / R = (S^c \circ R^\cup)^c$

B. Jónsson and A. Tarski studied relation algebras inspired by the algebra of binary relations on a set. B. Jónsson further studied residuated structures with C. Tsirikas (Boolean monoids). Our interest with GBI algebras partly stems from these contributions.

Given a set P for binary relations $R, S \in \mathcal{P}(P \times P)$, we define

- $R \wedge S = R \cap S$
- $R \vee S = R \cup S$
- $R \cdot S = R \circ S$ (relational composition)
- $R \rightarrow S = R^c \cup S = (R \cap S^c)^c$
- $R \backslash S = (R^\cup \circ S^c)^c$ (where R^\cup is the converse of R)
- $S / R = (S^c \circ R^\cup)^c$

This is an example of a GBI algebra, and part of its special nature is the fact that the Heyting algebra reduct is actually Boolean. We consider generalizations of these algebras called weakening relation algebras.

On linearly ordered sets, such relations have graphs that are left-up closed. Some can be obtained by graphs of functions by closing left-up.

We now explain why $Wk(\mathbf{P})$ supports a structure of a GBI-algebra, under union and intersection, and composition of relations.

A *weak conucleus* on a residuated lattice \mathbf{A} is an interior operator σ on \mathbf{A} such that $\sigma(x)\sigma(y) \leq \sigma(xy)$, for all $x, y \in \mathbf{A}$. Then $\sigma[\mathbf{A}] = (\sigma[A], \wedge_\sigma, \vee, \cdot, \backslash_\sigma, /_\sigma)$ is a residuated lattice-ordered semigroup, where $x \bullet_\sigma y = \sigma(x \bullet y)$, where $\bullet \in \{\wedge, \backslash, /\}$. We are interested in the cases where this algebra also has an identity element e and hence $(\sigma[A], e)$ is a residuated lattice.

A *topological weak conucleus* further satisfies $\sigma(x) \wedge \sigma(y) \leq \sigma(x \wedge y)$. So, a topological weak conucleus on a GBI-algebra \mathbf{A} is a weak conucleus on both the residuated lattice and the Brouwerian algebra reducts of \mathbf{A} .

A *weak conucleus* on a residuated lattice \mathbf{A} is an interior operator σ on \mathbf{A} such that $\sigma(x)\sigma(y) \leq \sigma(xy)$, for all $x, y \in \mathbf{A}$. Then $\sigma[\mathbf{A}] = (\sigma[A], \wedge_\sigma, \vee, \cdot, \backslash_\sigma, /_\sigma)$ is a residuated lattice-ordered semigroup, where $x \bullet_\sigma y = \sigma(x \bullet y)$, where $\bullet \in \{\wedge, \backslash, /\}$. We are interested in the cases where this algebra also has an identity element e and hence $(\sigma[A], e)$ is a residuated lattice.

A *topological weak conucleus* further satisfies $\sigma(x) \wedge \sigma(y) \leq \sigma(x \wedge y)$. So, a topological weak conucleus on a GBI-algebra \mathbf{A} is a weak conucleus on both the residuated lattice and the Brouwerian algebra reducts of \mathbf{A} .

Given a residuated lattice \mathbf{A} and a positive idempotent element p , the map σ_p , where $\sigma_p(x) = p \backslash x / p$, is a topological weak conucleus called the *double division conucleus by p* .

A *weak conucleus* on a residuated lattice \mathbf{A} is an interior operator σ on \mathbf{A} such that $\sigma(x)\sigma(y) \leq \sigma(xy)$, for all $x, y \in \mathbf{A}$. Then $\sigma[\mathbf{A}] = (\sigma[A], \wedge_\sigma, \vee, \cdot, \backslash_\sigma, /_\sigma)$ is a residuated lattice-ordered semigroup, where $x \bullet_\sigma y = \sigma(x \bullet y)$, where $\bullet \in \{\wedge, \backslash, /\}$. We are interested in the cases where this algebra also has an identity element e and hence $(\sigma[A], e)$ is a residuated lattice.

A *topological weak conucleus* further satisfies $\sigma(x) \wedge \sigma(y) \leq \sigma(x \wedge y)$. So, a topological weak conucleus on a GBI-algebra \mathbf{A} is a weak conucleus on both the residuated lattice and the Brouwerian algebra reducts of \mathbf{A} .

Given a residuated lattice \mathbf{A} and a positive idempotent element p , the map σ_p , where $\sigma_p(x) = p \backslash x / p$, is a topological weak conucleus called the *double division conucleus by p* . Also, p is the identity element $\sigma_p(\mathbf{A})$; we denote the resulting residuated lattice/GBI-algebra $(\sigma_p(\mathbf{A}), p)$ by $p \backslash \mathbf{A} / p$.

A *weak conucleus* on a residuated lattice \mathbf{A} is an interior operator σ on \mathbf{A} such that $\sigma(x)\sigma(y) \leq \sigma(xy)$, for all $x, y \in \mathbf{A}$. Then $\sigma[\mathbf{A}] = (\sigma[A], \wedge_\sigma, \vee, \cdot, \backslash_\sigma, /_\sigma)$ is a residuated lattice-ordered semigroup, where $x \bullet_\sigma y = \sigma(x \bullet y)$, where $\bullet \in \{\wedge, \backslash, /\}$. We are interested in the cases where this algebra also has an identity element e and hence $(\sigma[A], e)$ is a residuated lattice.

A *topological weak conucleus* further satisfies $\sigma(x) \wedge \sigma(y) \leq \sigma(x \wedge y)$. So, a topological weak conucleus on a GBI-algebra \mathbf{A} is a weak conucleus on both the residuated lattice and the Brouwerian algebra reducts of \mathbf{A} .

Given a residuated lattice \mathbf{A} and a positive idempotent element p , the map σ_p , where $\sigma_p(x) = p \backslash x / p$, is a topological weak conucleus called the *double division conucleus by p* . Also, p is the identity element $\sigma_p(\mathbf{A})$; we denote the resulting residuated lattice/GBI-algebra $(\sigma_p(\mathbf{A}), p)$ by $p \backslash \mathbf{A} / p$.

Given a poset $\mathbf{P} = (P, \leq)$, we set $\mathbf{A} = \text{Rel}(P)$, to be the involutive GBI algebra of all binary relations on the set P . Note that $p = \leq$ is a positive idempotent element of \mathbf{A} . It is easy to see that $p \backslash \mathbf{A} / p$ is exactly $Wk(\mathbf{P})$, so the latter is a GBI-algebra.

If \mathbf{A} is involutive then so is $p \backslash \mathbf{A} / p$ and the latter is a subalgebra of \mathbf{A} with respect to the operations $\wedge, \vee, \cdot, +, \sim, -$. Recall that an *involutive* residuated lattice is an expansion of a residuated lattice with an extra constant 0 such that $\sim(-x) = x = -(\sim x)$, where $\sim x = x \backslash 0$ and $-x = 0 / x$; we also define $x + y = \sim(-y \cdot -x)$.

If \mathbf{A} is involutive then so is $p \backslash \mathbf{A} / p$ and the latter is a subalgebra of \mathbf{A} with respect to the operations $\wedge, \vee, \cdot, +, \sim, -$. Recall that an *involutive* residuated lattice is an expansion of a residuated lattice with an extra constant 0 such that $\sim(-x) = x = -(\sim x)$, where $\sim x = x \backslash 0$ and $-x = 0 / x$; we also define $x + y = \sim(-y \cdot -x)$.

We note that we also have that $Wk(\mathbf{P}) \cong Res(\mathcal{O}(\mathbf{P}))$.

If \mathbf{A} is involutive then so is $p \backslash \mathbf{A} / p$ and the latter is a subalgebra of \mathbf{A} with respect to the operations $\wedge, \vee, \cdot, +, \sim, -$. Recall that an *involutive* residuated lattice is an expansion of a residuated lattice with an extra constant 0 such that $\sim(-x) = x = -(\sim x)$, where $\sim x = x \backslash 0$ and $-x = 0 / x$; we also define $x + y = \sim(-y \cdot -x)$.

We note that we also have that $Wk(\mathbf{P}) \cong Res(\mathcal{O}(\mathbf{P}))$. Recall that for a complete join semilattice \mathbf{L} , $Res(\mathbf{L})$ denotes the residuated lattice of all residuated maps on \mathbf{L} ; here a map f on a poset \mathbf{P} is called *residuated* if there exists a map f^* on P such that $f(x) \leq y$ iff $x \leq f^*(y)$, for all $x, y \in P$.

The study of congruences of the algebraic models is important in determining subdirectly irreducibles, subvarieties, deduction theorems. We prove that congruences on an algebra correspond to specific subsets. As in the case of group theory (normal subgroups) this proves to be a substantial simplification.

The study of congruences of the algebraic models is important in determining subdirectly irreducibles, subvarieties, deduction theorems. We prove that congruences on an algebra correspond to specific subsets. As in the case of group theory (normal subgroups) this proves to be a substantial simplification.

In residuated lattices congruences correspond to *normal submonoid filters*.

The study of congruences of the algebraic models is important in determining subdirectly irreducibles, subvarieties, deduction theorems. We prove that congruences on an algebra correspond to specific subsets. As in the case of group theory (normal subgroups) this proves to be a substantial simplification.

In residuated lattices congruences correspond to *normal submonoid filters*. Given $a, x \in A$ we define $\rho'_a x = ax/a$ and $\lambda'_a(x) = a \backslash xa$ (which are akin to conjugates in group theory). A subset is called *normal* if it is closed under ρ'_a and λ'_a for all $a \in A$.

In residuated lattices congruences correspond to *normal submonoid filters*. Given $a, x \in A$ we define $\rho'_a x = ax/a$ and $\lambda'_a(x) = a \backslash xa$ (which are akin to conjugates in group theory). A subset is called *normal* if it is closed under ρ'_a and λ'_a for all $a \in A$.

It is known that if θ is a congruence on \mathbf{A} then $\uparrow[1]_\theta$, the upset of the equivalence class of 1, is a normal multiplicative filter. Conversely, if F is a normal multiplicative filter of a residuated lattice \mathbf{A} , then the relation θ_F is a congruence on \mathbf{A} , where $a \theta_F b$ iff $a \backslash b \wedge b \backslash a \in F$.

Alternative subsets to F include convex normal (for $\rho_a x = (ax/a) \wedge 1$ and $\lambda_a(x) = (a \backslash xa) \wedge 1$) subalgebras, such as $\{x : f \leq x \leq 1/f, f \in F\}$ and also convex normal (for ρ, λ) negative submonoids, such as the negative cone of F : $\{x \in F : x \leq 1\}$.

Alternative subsets to F include convex normal (for $\rho_a x = (ax/a) \wedge 1$ and $\lambda_a(x) = (a \backslash xa) \wedge 1$) subalgebras, such as $\{x : f \leq x \leq 1/f, f \in F\}$ and also convex normal (for ρ, λ) negative submonoids, such as the negative cone of F : $\{x \in F : x \leq 1\}$.

Note that if A is a Brouwerian or a Heyting algebra, then all notions coincide: normal multiplicative filters, convex normal subalgebras, and convex normal negative submonoids, are usual lattice filters.

Alternative subsets to F include convex normal (for $\rho_a x = (ax/a) \wedge 1$ and $\lambda_a(x) = (a \backslash xa) \wedge 1$) subalgebras, such as $\{x : f \leq x \leq 1/f, f \in F\}$ and also convex normal (for ρ, λ) negative submonoids, such as the negative cone of F : $\{x \in F : x \leq 1\}$.

Note that if A is a Brouwerian or a Heyting algebra, then all notions coincide: normal multiplicative filters, convex normal subalgebras, and convex normal negative submonoids, are usual lattice filters.

GBI-congruences are RL-congruences with further closure conditions. As a result the equivalence class of 1 is a normal multiplicative filter with further closure conditions. We identify these as closure under $r_{a,b}(x) = (a \rightarrow b)/(xa \rightarrow b)$ and $s_{a,b}(x) = (a \rightarrow bx)/(a \rightarrow b)$, for all a, b .

$$v_{a,b}(x) = ab \rightarrow (a \wedge x)b,$$

$$v'_{a,b}(x) = ab \rightarrow a(b \wedge x), \text{ and}$$

$$w(x) = \top \backslash x / \top, \text{ for all } a, b.$$

As a result we obtain a parameterized local deduction theorem for the GBI.

Starting from GBI-algebras we can present a display calculus for it, in a natural way. However, a standard *Genzen-style* formalism also enjoys enough display properties and is simpler. The following calculus is well known, starting from the relevance logic community.

We consider the set of GBI-formulas Fm and define the free algebra W over Fm with two operations \circ (also denoted by comma) and \bigwedge (also denoted by semicolon). A sequent (also called a bunch) is an expression of the form $x \Rightarrow a$, where $x \in W$ and $a \in Fm$. For example,

$$(q \bigwedge (p \rightarrow r)) \circ (p \cdot q) \Rightarrow (p \rightarrow q) \setminus (q \wedge r)$$

$$(q \bigwedge (p \rightarrow r)) \circ (p \cdot q) \Rightarrow (p \rightarrow q) \setminus (q \wedge r)$$

We will consider extensions by any equations over the signature $\{\vee, \wedge, \cdot, 1\}$ of this calculus and study cut elimination, decidability, finite model property, finite embeddability property.

The *multiplicative lenght* of a sequent is defined along an oriented path by counting the maximum numbers of \circ , \cdot in negative position and of \backslash , $/$ in positive position. Note that the multiplicative length does not increase upwards by the rules. Care is needed for $(\rightarrow L)$:
