

# Performance Prediction for Neural Architecture Search

Gabriela Kadlecová, Petra Vidnerová,  
Jovita Lukasik, Martin Pilát,  
Mahmoud Safari, Roman Neruda, Frank Hutter

**Hora Informaticae, March 19, 2024**

# Outline

## Introduction – high level overview

- ▶ AutoML and Neural Architecture Search
- ▶ Search Spaces and objectives
- ▶ Search algorithms
- ▶ Speedup techniques

## Performance prediction

- ▶ Analyzed search spaces
- ▶ Performance prediction
- ▶ Zero-cost Proxies

## New predictor – graph properties

- ▶ Motivation, experimental results

# AutoML and Neural Architecture Search

## Automated Machine Learning

*The process of automating all steps in the machine learning pipeline, from data cleaning, to feature engineering and selection, to hyperparameter and architecture search.*

## Neural Architecture Search (NAS)

*Automating the design of neural network architecture. Given a problem, NAS looks for an optimal architecture.*

Handwritten signature or initials.

# Neural Architecture Search (NAS)

- ▶ Optimization problem
- ▶ Minimize given objectives over the given search space
- ▶ Our focus - speed up the optimization process using performance prediction

# Search Spaces

- ▶ Space of possible solutions (architectures)
- ▶ Trade-off between human bias and search efficiency
  
- ▶ Macro search spaces
  - ▶ Encode the entire architecture
  - ▶ Focus on macro-level hyperparameters
  - ▶ Slow to search
- ▶ Chain-structured search spaces
  - ▶ A sequential chain of operation layers
  - ▶ Easy to design and implement
  - ▶ Lower chance of discovering novel architecture
- ▶ Cell-based search spaces
  - ▶ Search for **cells**
  - ▶ Skeleton fixed
  - ▶ Popular, but have limits

# Speed-up Techniques

## Parallelisation

- ▶ Easy, parallel objective evaluation
- ▶ Evolution with islands

## Performance prediction

- ▶ Regression of the objective
- ▶ Learning curve extrapolation
- ▶ Zero-cost proxies

## Meta-learning

- ▶ Re-using information from previous experiments

# Our work

## Setting

- ▶ What benchmarks and datasets?
- ▶ Performance prediction details
- ▶ Zero-cost proxies

## Goals

- ▶ Analyze zero-cost proxies as predictors
- ▶ Properties of the neural graph as a novel predictor
- ▶ Interpretability analysis of predictions
- ▶ Compare with predictors from related work

A handwritten signature or logo in blue ink, located in the bottom right corner of the slide. It appears to be a stylized, cursive signature.

# NAS Benchmarks

- ▶ Datasets of precomputed objectives on selected tasks
- ▶ Enables experiments and comparison of NAS algorithms, performance prediction algorithms
- ▶ Important for reproducible research
  
- ▶ NAS-Bench-101, NAS-Bench-201, NAS-Bench-301
- ▶ HW-NAS-Bench, TransNAS-Bench-101, robustness NB201

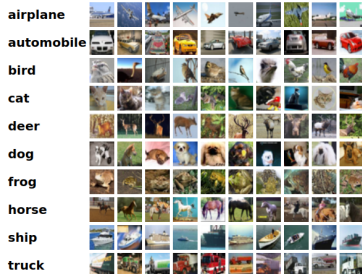

Source: NAS-Bench-201: Extending the scope of reproducible NAS. ICLR 2020

# Image Classification Datasets

## CIFAR10, CIFAR100

- ▶ Learning Multiple Layers of Features from Tiny Images, Alex Krizhevsky, 2009.
- ▶ 10/100 classes
- ▶ 60k images, 32x32 pixels

## ImageNet-16-120

- ▶ A downsampled variant of Imagenet as an alternative to the Cifar dataset, Chrabaszc et al, 2017
- ▶ 1000 classes

# Limits of benchmarks

## NAS-Bench-201

- ▶ Evaluated for different datasets and objectives
- ▶ Total of 15 625 candidates
- ▶ However, some of them are isomorphic
- ▶ Some have invalid branches
- ▶ The valid and unique set is quite small

## NB101, NB301

- ▶ Larger, but evaluated only on CIFAR10
- ▶ Only one objective (accuracy)
- ▶ Cell-based – but models like LLMs are different

A handwritten signature in black ink, appearing to be 'SFA'.

# Performance Prediction

## Predict objectives

- ▶ Imprecise prediction is enough (coarse to grain)
- ▶ Ranking is enough (who is the best)

## Our goals

- ▶ Performance prediction of diverse objectives
- ▶ Accuracy, robustness, energy
- ▶ Exploring/combining zero cost proxies
- ▶ Proposal of new network encodings

# Methodology

## Regression

- ▶ Random forest regressor
- ▶ Predict accuracy or other metrics

## Input data – network encodings

- ▶ Zero cost proxies
- ▶ One hot encoding (of chosen operations)
- ▶ Graph properties

## Experiments

- ▶ Analyze predictions
- ▶ Compare different network encodings, predictors

# Zero-cost proxies (ZCP)

- ▶ Fast to compute metrics that correlate with accuracy
- ▶ Zero-cost ... because we don't train the network at all!
- ▶ Some proxies depend on input data
- ▶ Other use artificial batches, e.g. a batch full of 1

## How to compute ZCP?

- ▶ Sample one minibatch of data (or create an artificial batch)
- ▶ Pass it through the (untrained) network
- ▶ Compute a metric as a function of the forward pass and/or the gradient

# ZCP in performance prediction

## Main approaches

- ▶ Direct approximation of performance – choose nets with the highest score
- ▶ Warm-start search – initial generation are top-scored nets
- ▶ ZCP as net encoding – fit a regressor on multiple ZCP, predict performance

## Examples of proxies

- ▶ flops, params – just simple metrics (no batch pass)
- ▶ synflow – from network pruning, product of network parameters
- ▶ nwot – activation of different ReLU regions (variance between batch examples)

# ZCP limitations

- ▶ For NB201, ZCP correlate surprisingly well with accuracy
- ▶ On some other searchspaces, the correlation is rather low
- ▶ We discovered the reason for the good correlation on NB201
- ▶ For proxies like nwot, l2\_norm, the score directly depends on the number of convolutions in the network

All networks in nb201 on cifar10 - l2\_norm by #convs

# Properties of the neural graph

- ▶ Inspired by the finding, we look at properties of the network graph – paths, counts, ...
- ▶ Node degree (c3x3, skip) means input degree counting only conv3x3 and skip
- ▶ Similarly, max path computes the maximum path over allowed operations

Node degree  
(c3x3, skip): 2

Max path  
(c3x3, skip): 3

Max path  
(skip): 1

# Properties of the neural graph

- ▶ Number of operations
- ▶ Min path from input over operations  $O$
- ▶ Max path from input to over operations  $O$
- ▶ Out degree of the input node counting only operations  $O$
- ▶ In degree of the output node counting only operations  $O$
- ▶ Mean in/out degree of intermediate nodes counting only operations  $O$

## Advantages

- ▶ Simple, interpretable, fast to compute

## Disadvantages

- ▶ Highly correlated, dependent on search space

# Accuracy prediction

## Usage in performance prediction

- ▶ Gathering all properties, we use them as input data to a random forest regressor
- ▶ We compare with other network encodings – all ZCP, one-hot encoding (OH), and their combinations

## Results

- ▶ Our results (GRAF) are better than ZCP and OH
- ▶ ZCP combined with network properties is the best

*SEA*

# Interpretable prediction

- ▶ For network properties and ZCP, we compute Shapley coefficients (considers feature set importance)
- ▶ We look at the most important features
- ▶ Results – different features are important for diverse tasks
- ▶ nwot is important for CIFAR10, but not for autoencoder
- ▶ autoencoder needs skip connections – result from related work!

NB201 - cifar-10		TNB101-micro - autoencoder	
Feature name	Mean rank	Feature name	Mean rank
jacov	0.00	min path over skip	0.00
nwot	1.12	jacov	1.00
flops	3.62	fisher	2.00
synflow	4.08	min path over [skip,C3x3]	5.50
min path over [skip,C3x3,C1x1]	4.78	snip	5.58
params	5.04	min path over [skip,C1x1]	5.64
epe_nas	6.04	grad_norm	6.64
zen	6.36	zen	8.08
min path over [skip,C3x3]	11.08	grasp	9.34
min path over skip	11.88	l2_norm	9.74

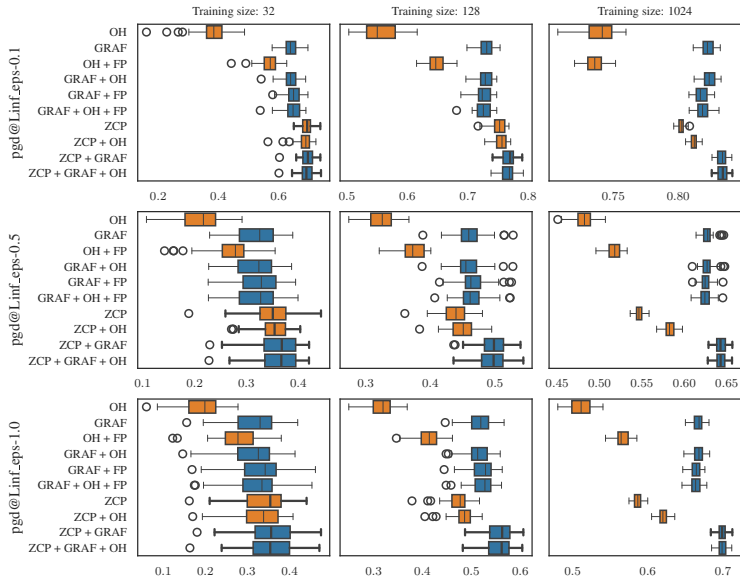

# HW metrics prediction

Prediction of EDGEGPU energy, random forest.

- ▶ HW metrics differ in difficulty of prediction
- ▶ edgegpu energy is one of difficult tasks

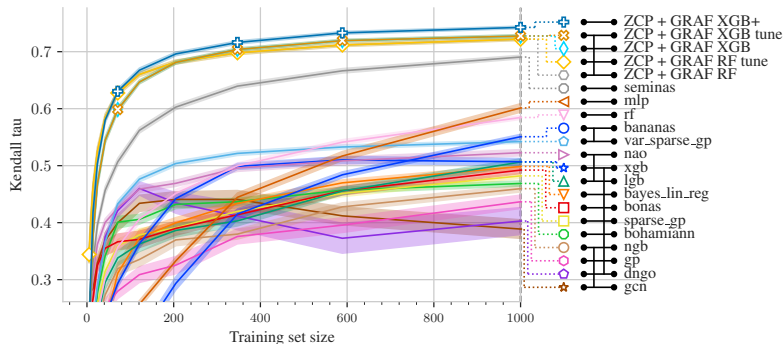

# Robustness prediction

SEA

# Comparison with existing predictors – NB101, CIFAR10

- ▶ Same experiment as in a predictor survey [1]
- ▶ Outperforms all available predictors
- ▶ Some predictors take much longer to train, e.g. graph neural networks!

[1] Colin White, Arber Zela, Binxin Ru, Yang Liu, & Frank Hutter (2021). How Powerful are Performance Predictors in Neural Architecture Search?. In Advances in Neural Information Processing Systems.

# Usage in the NAS process – ImageNet16-120 search

# Discussion and future work

## Pros

- ▶ Better and faster than most predictors
- ▶ Great interpretability
- ▶ Works across tasks and search spaces
- ▶ Baseline for complex predictors

## Cons

- ▶ Properties need to be used with ZCP for best performance
- ▶ Some graph neural networks with ZCP can be better

## Future work

- ▶ Extension to transformer or LLM search spaces
- ▶ Study why ZCP are still needed

# Thank you! Questions?
