

# INTERIOR POINT METHODS FOR LARGE-SCALE NONLINEAR PROGRAMMING

Ladislav Lukšan, Jan Vlček  
Institute of Computer Science AVČR

## Contents:

- Introduction.
- Direction determination. Formulation of linear KKT equations.
- Iterative solution by conjugate gradients. The first-type preconditioners.
- Linear dependence of active constraints. Regularization.
- The second-type preconditioners.
- Step-length selection. Strategies for step-lengths restriction. Merit function. Restarts.
- Update of the barrier parameter.
- Computational results.

## Nonlinear programming problem:

Consider the problem

$$\begin{aligned} f(x) &\rightarrow \min, \\ c_I(x) &\leq 0, \\ c_E(x) &= 0, \end{aligned}$$

$I = \{1, \dots, m_I\}$ ,  $E = \{m_I + 1, \dots, m_I + m_E\}$ , where functions  $f(x)$ ,  $c_I(x)$ ,  $c_E(x)$  are twice continuously differentiable. Necessary (KKT) conditions have the following form (we assume the standard constraint qualifications):

$$\begin{aligned} g(x, u) &= 0, \\ c_I(x) &\leq 0, \quad u_I \geq 0, \quad u_I^T c_I(x) = 0, \\ c_E(x) &= 0, \end{aligned}$$

where

$$g(x, u) = \nabla f(x) + A_I(x)u_I + A_E(x)u_E,$$

and  $A_I(x) = [\nabla c_i(x) : i \in I]$ ,  $A_E(x) = [\nabla c_i(x) : i \in E]$ . Here  $u_I \in R^{m_I}$ ,  $u_E \in R^{m_E}$  are vectors of Lagrange multipliers.

## Interior point (IP) principle:

$$\begin{aligned} f(x) - \mu e^T \ln(S_I)e &\rightarrow \min, \\ c_I(x) + s_I &= 0, \\ c_E(x) &= 0, \end{aligned}$$

where  $s_I > 0$  is a slack vector,  $e$  is the vector with unit elements and  $S_I = \text{diag}(s_i : i \in I)$  (we assume that  $\mu \rightarrow 0$ ).

Necessary (KKT) conditions have the following form:

primal formulation	primal-dual formulation
$g(x, u) = 0,$	$g(x, u) = 0,$
$U_I e - \mu S_I^{-1} e = 0,$	$S_I U_I e - \mu e = 0,$
$c_I(x) + s_I = 0,$	$c_I(x) + s_I = 0,$
$c_E(x) = 0,$	$c_E(x) = 0,$

where

$$g(x, u) = \nabla f(x) + A_I(x)u_I + A_E(x)u_E,$$

and  $S_I = \text{diag}(s_i : i \in I)$ ,  $U_I = \text{diag}(u_i : i \in I)$ . The inequalities  $s_i > 0$  and  $u_i > 0$  have to be satisfied in all iterations. Primal-dual formulation leads to more effective algorithms.

## Direction determination (line-search approach):

Linearization - the Newton method

$$\begin{bmatrix} G & 0 & A_I & A_E \\ 0 & U_I & S_I & 0 \\ A_I^T & I & 0 & 0 \\ A_E^T & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta s_I \\ \Delta u_I \\ \Delta u_E \end{bmatrix} = - \begin{bmatrix} g \\ S_I U_I e - \mu e \\ c_I + s_I \\ c_E \end{bmatrix},$$

where  $g = g(x, u)$  and

$$G = G(x, u) = \nabla^2 f(x) + \sum_{i \in I \cup E} u_i \nabla^2 c_i(x).$$

We assume that matrix of this system is nonsingular. Elimination of  $\Delta s_I$ :

$$\Delta s_I = -U_I^{-1} S_I (u_I + \Delta u_I) + \mu U_I^{-1} e$$

Active and inactive constraints ( $\varepsilon_I > 0$ ).

$$\hat{s}_I \leq \varepsilon_I \hat{u}_I \quad - \quad \text{active constraints}$$

$$\check{s}_I > \varepsilon_I \check{u}_I \quad - \quad \text{inactive constraints}$$

Elimination of inactive constraints:

$$\Delta \check{u}_I = \check{S}_I^{-1} \check{U}_I (\check{c}_I + \check{A}_I^T \Delta x) + \mu \check{S}_I^{-1} e$$

The final equations

$$\begin{bmatrix} \hat{G} & \hat{A}_I & A_E \\ \hat{A}_I^T & -\hat{U}_I^{-1}\hat{S}_I & 0 \\ A_E^T & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta \hat{u}_I \\ \Delta u_E \end{bmatrix} = - \begin{bmatrix} \hat{g} \\ \hat{c}_I + \mu \hat{U}_I^{-1}e \\ c_E \end{bmatrix},$$

where

$$\begin{aligned} \hat{G} &= G + \check{A}_I \check{S}_I^{-1} \check{U}_I \check{A}_I^T, \\ \hat{g} &= g + \check{A}_I \check{S}_I^{-1} \check{U}_I \check{c}_I + \mu \check{A}_I \check{S}_I^{-1} e. \end{aligned}$$

Both matrices  $\hat{G}$  and  $\hat{U}_I^{-1}\hat{S}_I$  are bounded (if  $G$  and  $A$  are bounded) and if the strict complementarity conditions hold, then  $\lim_{\mu \rightarrow 0} \hat{U}_I^{-1}\hat{S}_I = 0$ . After substitution we obtain

$$\begin{aligned} \Delta \hat{s}_I &= -\hat{U}_I^{-1}\hat{S}_I(\hat{u}_I + \Delta \hat{u}_I) + \mu \hat{U}_I^{-1}e, \\ \Delta \check{s}_I &= -(\check{c}_I + \check{A}_I^T \Delta x + \check{s}_I). \end{aligned}$$

Vector  $\Delta \hat{u}_I$  is determined as an inexact solution of the above system, vector  $\Delta \check{u}_I$  is obtained by direct elimination.

## Indefinitely preconditioned conjugate gradient method:

$$K\bar{d} = \begin{bmatrix} \hat{G} & \hat{A} \\ \hat{A}^T & -\hat{M} \end{bmatrix} \begin{bmatrix} d \\ \hat{d} \end{bmatrix} = \begin{bmatrix} b \\ \hat{b} \end{bmatrix} = \bar{b},$$

where  $\hat{A} = [\hat{A}_I, A_E]$  and  $\hat{M} = \text{diag}(\hat{M}_I, 0)$ . Here  $\hat{M}_I = \hat{U}_I^{-1} \hat{S}_I$  is a positive definite diagonal matrix. We assume that matrix  $K$  is nonsingular, which implies that  $A_E$  has a full column rank.

The first class of indefinite preconditioners:

$$C = \begin{bmatrix} \hat{D} & \hat{A} \\ \hat{A}^T & -\hat{M} \end{bmatrix},$$

where  $\hat{D}$  is a positive definite diagonal matrix derived from the diagonal of  $\hat{G}$ . Expressions for matrices  $K$  and  $C$  imply that

$$C^{-1} = \begin{bmatrix} \hat{P} & \hat{Q} \\ \hat{Q}^T & -(\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M})^{-1} \end{bmatrix},$$

where  $\hat{P} = \hat{D}^{-1} - \hat{D}^{-1} \hat{A} (\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M})^{-1} \hat{A}^T \hat{D}^{-1}$ ,  
 $\hat{Q} = \hat{D}^{-1} \hat{A} (\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M})^{-1}$ .

The preconditioned matrix

$$KC^{-1} = \begin{bmatrix} I + (\hat{G} - \hat{D})\hat{P} & (\hat{G} - \hat{D})\hat{Q} \\ 0 & I \end{bmatrix},$$

Basic theorems:

**Theorem 1.** Consider preconditioner  $C$  applied to system  $K\bar{d} = \bar{b}$  and assume that  $\hat{G} - \hat{D}$  is nonsingular. Then matrix  $KC^{-1}$  has at least  $\hat{m}_I + 2m_E$  unit eigenvalues but at most  $\hat{m}_I + m_E$  linearly independent eigenvectors corresponding to these eigenvalues exist. The other eigenvalues of matrix  $KC^{-1}$  are exactly eigenvalues of matrix  $Z_E^T \tilde{G} Z_E (Z_E^T \tilde{D} Z_E)^{-1}$ , where  $[Z_E, A_E]$  is a nonsingular square matrix,  $Z_E^T A_E = 0$ ,  $Z_E^T Z_E = I$  and where

$$\begin{aligned} \tilde{G} &= \hat{G} + \hat{A}_I \hat{M}_I^{-1} \hat{A}_I^T, \\ \tilde{D} &= \hat{D} + \hat{A}_I \hat{M}_I^{-1} \hat{A}_I^T. \end{aligned}$$

If  $Z_E^T \tilde{G} Z_E$  is positive definite then all eigenvalues are positive.

**Theorem 2.** Consider preconditioner  $C$  applied to system  $K\bar{d} = \bar{b}$  and assume that  $\hat{G} - \hat{D}$  is nonsingular. Then the Krylov subspace  $\mathcal{K}$  defined by matrix  $KC^{-1}$  and vector  $\bar{r} \in R^{n+\hat{m}_I+m_E}$ , has a dimension of at most  $\min(n+1, n-m_E+2)$ .

The preconditioned CG method:

$$K\bar{d} = \begin{bmatrix} \hat{G} & \hat{A} \\ \hat{A}^T & -\hat{M} \end{bmatrix} \begin{bmatrix} d \\ \hat{d} \end{bmatrix} = \begin{bmatrix} b \\ \hat{b} \end{bmatrix} = \bar{b},$$

### Algorithm PCG

$$\begin{aligned} d & - \text{given}, & \hat{d} & := 0, \\ r & := b - \hat{G}d - \hat{A}\hat{d}, & \hat{r} & := \hat{b} - \hat{A}^T d + \hat{M}\hat{d}, \\ \beta & := 0, \end{aligned}$$

**while**  $\|r\| > \omega\|b\|$  or  $\|\hat{r}\| > \omega\|\hat{b}\|$  **do**

$$\begin{aligned} \hat{t} & := (\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M})^{-1} (\hat{A}^T \hat{D}^{-1} r - \hat{r}), \\ t & := \hat{D}^{-1} (r - \hat{A}\hat{t}), \\ \gamma & := r^T t + \hat{r}^T \hat{t}, & \beta & := \beta\gamma, \\ p & := t + \beta p, & \hat{p} & := \hat{t} + \beta\hat{p}, \\ q & := \hat{G}p + \hat{A}\hat{p}, & \hat{q} & := \hat{A}^T p - \hat{M}\hat{p}, \\ \alpha & := p^T q + \hat{p}^T \hat{q}, & \alpha & := \gamma/\alpha, \\ d & := d + \alpha p, & \hat{d} & := \hat{d} + \alpha\hat{p}, \\ r & := r - \alpha q, & \hat{r} & := \hat{r} - \alpha\hat{q}, \\ \beta & := 1/\gamma \end{aligned}$$

**end while.**

**Theorem 3.** Consider Algorithm PCG with preconditioner  $C$  applied to system  $K\bar{d} = \bar{b}$ . Assume that initial  $\bar{d}$  is chosen in such a way that  $\hat{r} = 0$  at the start of the algorithm. Let matrix  $Z_E^T \tilde{G} Z_E$  be positive definite. Then:

- (a) Vector  $d^*$  (the first part of vector  $\bar{d}^*$  which solves equation  $K\bar{d} = \bar{b}$ ) is found after  $n - m_E$  iterations at most.
- (b) The algorithm cannot break down before  $d^*$  is found.
- (c) Error  $\|d - d^*\|$  converges to zero at least  $R$  - linearly with quotient

$$\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1},$$

where  $\kappa$  is the spectral condition number of matrix  $Z_E^T \tilde{G} Z_E (Z_E^T \tilde{D} Z_E)^{-1}$ .

- (d) If  $d = d^*$ , then also  $\hat{d}_I = \hat{d}_I^*$  and  $d_E^*$  can be determined by the formula

$$d_E^* = d_E + (A_E^T \tilde{D}^{-1} A_E)^{-1} A_E^T \tilde{D}^{-1} r.$$

Theorem 3 assumes that  $\hat{r} = 0$  at the start of Algorithm PCG. This condition is satisfied if we set  $\hat{d} = 0$  and

$$d = (\hat{A}^T \hat{D}^{-1} \hat{A})^{-1} \hat{A}^T \hat{D}^{-1} \hat{b}.$$

In Algorithm PCG, the sparse Choleski decomposition (complete or incomplete) of matrix  $\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M}$  is used instead of its inversion. Unfortunately, this matrix can be dense if  $\hat{A}$  has dense rows. Assume that  $\hat{A}^T = [\hat{A}_s^T, \hat{A}_d^T]$  and  $\hat{D} = \text{diag}(\hat{D}_s, \hat{D}_d)$ , where

$$\hat{M}_s = \hat{A}_s^T \hat{D}_s^{-1} \hat{A}_s + \hat{M}$$

is sparse and  $\hat{A}_d$  consists of dense rows. Then

$$\begin{aligned} (\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M})^{-1} &= (\hat{M}_s + \hat{A}_d^T \hat{D}_d^{-1} \hat{A}_d)^{-1} \\ &= \hat{M}_s^{-1} - \hat{M}_s^{-1} \hat{A}_d^T \hat{M}_d^{-1} \hat{A}_d \hat{M}_s^{-1}, \end{aligned}$$

where

$$\hat{M}_d = \hat{D}_d + \hat{A}_d \hat{M}_s^{-1} \hat{A}_d^T$$

is a (low-dimensional) dense matrix. Again the sparse Choleski decomposition of matrix  $\hat{M}_s$  is used instead of its inversion.

## Linear dependence of gradients of active constraints:

We use a perturbation of  $\hat{M}$  to eliminate singularity (or near singularity) of matrix  $\hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M}$ . Thus we solve equation

$$K \bar{d} = \begin{bmatrix} \hat{G} & \hat{A} \\ \hat{A}^T & -(\hat{M} + \hat{E}) \end{bmatrix} \begin{bmatrix} d \\ \hat{d} \end{bmatrix} = \begin{bmatrix} b \\ \hat{b} \end{bmatrix} = \bar{b}$$

and use preconditioner

$$C = \begin{bmatrix} \hat{D} & \hat{A} \\ \hat{A}^T & -(\hat{M} + \hat{E}) \end{bmatrix},$$

where  $\hat{E}$  is a (small) positive semidefinite diagonal matrix.

**Theorem 4.** Let  $\hat{d}(\varepsilon)$  be the solution of the perturbed system with  $\hat{G}$  nonsingular and  $\hat{E} = \varepsilon \hat{E}_0$ . Then

$$\frac{1}{2} \frac{d(\hat{d}^T(\varepsilon) \hat{E}_0 \hat{d}(\varepsilon))}{d\varepsilon} = -\hat{d}^T(\varepsilon) \hat{E}_0 (\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M} + \varepsilon \hat{E}_0)^{-1} \hat{E}_0 \hat{d}(\varepsilon).$$

If there is a number  $\bar{\varepsilon} \geq 0$  such that  $\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M} + \varepsilon \hat{E}_0$  is positive definite  $\forall \varepsilon \geq \bar{\varepsilon}$ , the above expression is negative  $\forall \varepsilon \geq \bar{\varepsilon}$  and  $\hat{d}^T(\varepsilon) \hat{E}_0 \hat{d}(\varepsilon) \rightarrow 0$  if  $\varepsilon \rightarrow \infty$ .

## Regularization:

Matrix  $\hat{C} = \hat{A}^T \hat{D}^{-1} \hat{A} + \hat{M}$  is at least positive semidefinite. We can use the Gill-Murray decomposition  $\hat{R}^T \hat{R} = \hat{C} + \hat{E}$ , where  $\hat{R}$  is an upper triangular matrix and  $\hat{E}$  is a small positive definite diagonal matrix. In the  $i$ -th elimination step, the pivot is changed so that

$$\hat{R}_{ii} = \max \left( |\hat{r}_{ii}|, \frac{\gamma_i}{\beta}, \delta \right),$$

where  $\hat{r}_{ii}$  is the pivot before correction,  $\beta^2 > \|\hat{C}\|$ ,  $\delta = \sqrt{\varepsilon_M} \|\hat{C}\|$  ( $\varepsilon_M$  – machine precision) and  $\gamma_i$  is the maximum absolute value of the off diagonal element in the  $i$ -th row. Then  $\hat{E}_{ii} = \hat{R}_{ii} - \hat{r}_{ii} \geq 0$ . Then we obtain the reasonable preconditioner

$$C = \begin{bmatrix} \hat{D} & \hat{A} \\ \hat{A}^T & -(\hat{M} + \hat{E}) \end{bmatrix}$$

and the regularized system

$$\begin{bmatrix} \hat{G} & \hat{A} \\ \hat{A}^T & -(\hat{M} + \hat{E}) \end{bmatrix} \begin{bmatrix} d \\ \hat{d} \end{bmatrix} = \begin{bmatrix} b \\ \hat{b} \end{bmatrix}.$$

Another possibility is to compute an approximation  $\underline{\lambda}$  of the least eigenvalue of  $\hat{C}$  (from the Choleski decomposition) and replace  $M$  by  $M + \delta I$  if  $\underline{\lambda} \leq \delta$ .

## Additional indefinite preconditioners:

Let

$$C = \begin{bmatrix} \hat{B} & \hat{A} \\ \hat{A}^T & -\hat{N} \end{bmatrix},$$

where  $\hat{N} = \hat{M} + \hat{D} - \nu \hat{A}^T \hat{B}^{-1} \hat{A}$ ,  $\hat{B}$  is a nonsingular approximation of  $\hat{G}$  (usually  $\hat{B} = \hat{G}$ ),  $\hat{D}$  is a diagonal matrix such that  $\hat{M} + \hat{D}$  is positive definite and  $\nu$  is a parameter. Using  $\hat{B}$  or  $\hat{N}$  for block elimination, we obtain

$$C^{-1} = \begin{bmatrix} \hat{B}^{-1} - \hat{B}^{-1} \hat{A} \hat{C}^{-1} \hat{A}^T \hat{B}^{-1} & \hat{B}^{-1} \hat{A} \hat{C}^{-1} \\ \hat{C}^{-1} \hat{A}^T \hat{B}^{-1} & -\hat{C}^{-1} \end{bmatrix},$$

where  $\hat{C} = \hat{A}^T \hat{B}^{-1} \hat{A} + \hat{N}$  ( $\hat{C} = \hat{M} + \hat{D}$  if  $\nu = 1$ ), or

$$C^{-1} = \begin{bmatrix} \tilde{B}^{-1} & \tilde{B}^{-1} \hat{A} \hat{N}^{-1} \\ \hat{N}^{-1} \hat{A}^T \tilde{B}^{-1} & \hat{N}^{-1} \hat{A}^T \tilde{B}^{-1} \hat{A} \hat{N}^{-1} - \hat{N}^{-1} \end{bmatrix},$$

where  $\tilde{B} = \hat{B} + \hat{A} \hat{N}^{-1} \hat{A}^T$  ( $\hat{N} = \hat{M} + \hat{D}$  if  $\nu = 0$ ). Matrix  $\tilde{B}$  is usually sparse (it is dense when  $\hat{A}$  has dense columns). If  $\hat{B} = \hat{G}$ , then

$$KC^{-1} = \begin{bmatrix} I & 0 \\ (I - \hat{H}) \hat{A}^T \hat{G}^{-1} & \hat{H} \end{bmatrix},$$

where  $\hat{H} = (\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M}) \hat{C}^{-1}$ . Notice that  $\hat{H} = \hat{A}^T \tilde{B}^{-1} \hat{A} \hat{N}^{-1}$  if  $\hat{M} = 0$ .

**Theorem 5.** Consider preconditioner  $C$  with  $\hat{B} = \hat{G}$  and  $\hat{M} + \hat{D}$  positive definite applied to system  $K\bar{d} = \bar{b}$ . Then matrix  $KC^{-1}$  has at least  $n$  unit eigenvalues with a full system of  $n$  linearly independent eigenvectors. The other eigenvalues of  $KC^{-1}$  are exactly eigenvalues of matrix  $\hat{H} = (\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M}) \hat{C}^{-1}$ . If  $\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M}$  is positive definite then all eigenvalues are positive.

**Theorem 6.** Consider preconditioner  $C$  with  $\hat{B} = \hat{G}$  applied to system  $K\bar{d} = \bar{b}$ . Then the Krylov subspace  $\mathcal{K}$  defined by matrix  $KC^{-1}$  and vector  $\bar{r} \in R^{n+\hat{m}}$ , has a dimension of at most  $\hat{m} + 1$ .

**Theorem 7.** Consider the conjugate gradient method preconditioned by  $C$  with  $\hat{B} = \hat{G}$  and applied to system  $K\bar{d} = \bar{b}$ . Assume that initial  $\bar{d}$  is chosen in such a way that  $r = 0$  at the start of the algorithm. Let matrix  $\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M}$  be positive definite. Then:

- (a) Vector  $\bar{d}^*$  which solves equation  $K\bar{d} = \bar{b}$  is found after  $\hat{m}$  iterations at most.
- (b) The algorithm cannot break down before  $\bar{d}^*$  is found.
- (c) Error  $\|\hat{d} - \hat{d}^*\|$  converges to zero at least  $R$ -linearly with quotient  $(\sqrt{\kappa} - 1)/(\sqrt{\kappa} + 1)$ , where  $\kappa$  is the spectral condition number of matrix  $\hat{H} = (\hat{A}^T \hat{G}^{-1} \hat{A} + \hat{M}) \hat{C}^{-1}$ .

## Strategies for step-length restriction:

Let  $x_+ = x + \alpha \Delta x$ , where  $0 < \alpha < \bar{\alpha}$  with  $\bar{\alpha} = \min(1, \bar{\Delta}/\|\Delta x\|)$ . Since  $s_I^+ > 0$  and  $u_I^+ > 0$  have to hold, step-lengths for  $s_I$  and  $u_I$  have to be restricted. Strategy 1 uses individual step-lengths  $s_i^+ = s_i + \alpha_{s_i} \Delta s_i$  and  $u_i^+ = u_i + \alpha_{u_i} \Delta u_i$ , where

$$\begin{aligned} \alpha_{s_i} &= \alpha, & \Delta s_i &\geq 0, \\ \alpha_{s_i} &= \min \left( \alpha, -\gamma \frac{s_i}{\Delta s_i} \right), & \Delta s_i &< 0, \\ \alpha_{u_i} &= \alpha, & \Delta u_i &\geq 0, \\ \alpha_{u_i} &= \min \left( \alpha, -\gamma \frac{u_i}{\Delta u_i} \right), & \Delta u_i &< 0, \end{aligned}$$

( $0 < \gamma < 1$  is a coefficient close to unit). Other strategies require bounds

$$\begin{aligned} \bar{\alpha}_s &= \gamma \min_{i \in I, \Delta s_i < 0} \left( -\frac{s_i}{\Delta s_i} \right), \\ \bar{\alpha}_u &= \gamma \min_{i \in I, \Delta u_i < 0} \left( -\frac{u_i}{\Delta u_i} \right), \end{aligned}$$

where  $0 < \gamma < 1$  and define

$$\begin{aligned} s_I^+ = s_I(\alpha) &= s_I + \min(\alpha, \bar{\alpha}_s) \Delta s_I, \\ u_I^+ = u_I(\alpha) &= u_I + \min(\alpha, \bar{\alpha}_u) \Delta u_I. \end{aligned}$$

## Merit function for step-length selection:

$$\begin{aligned}
P(\alpha) &= f(x + \alpha \Delta x) - \mu e^T \ln(S_I(\alpha))e \\
&+ (u_I + \Delta u_I)^T (c_I(x + \alpha \Delta x) + s_I(\alpha)) \\
&+ (u_E + \Delta u_E)^T c_E(x + \alpha \Delta x) \\
&+ \frac{\sigma}{2} \|c_I(x + \alpha \Delta x) + s_I(\alpha) - E_I(u_I(\alpha) - u_I)\|^2 \\
&+ \frac{\sigma}{2} \|c_E(x + \alpha \Delta x) - E_E \alpha \Delta u_E\|^2,
\end{aligned}$$

where  $\sigma \geq 0$ .

**Theorem 8.** Let  $s_I > 0$ ,  $u_I > 0$  and let the triple  $\Delta x$ ,  $\Delta \hat{u}_I$ ,  $\Delta u_E$  be an inexact solution of a regularized system. Then

$$\begin{aligned}
P'(0) &= -(\Delta x)^T G \Delta x - (\Delta s_I)^T S_I^{-1} U_I \Delta s_I \\
&- \sigma (\|c_I + s_I\|^2 + \|c_E\|^2) \\
&+ (\Delta x)^T r + \sigma ((\hat{c}_I + \hat{s}_I)^T \hat{r}_I + c_E^T r_E).
\end{aligned}$$

where  $r$ ,  $\hat{r}_I$ ,  $r_E$  are parts of the residual vector. If

$$\sigma > -\frac{(\Delta x^T)G\Delta x + (\Delta s_I)^T S_I^{-1} U_I \Delta s_I}{\|c_I + s_I\|^2 + \|c_E\|^2}$$

and if  $(\Delta x)^T r + \sigma ((\hat{c}_I + \hat{s}_I)^T \hat{r}_I + c_E^T r_E)$  is sufficiently small, then

$$P'(0) < 0$$

## Restart:

If  $P'(0) \geq 0$ , then line-search usually fails. There are two basic possibilities.

- We recompute  $\sigma \geq 0$  so that

$$\sigma > -\frac{(\Delta x^T)G\Delta x + (\Delta s_I)^T S_I^{-1} U_I \Delta s_I}{\|c_I + s_I\|^2 + \|c_E\|^2}.$$

Then  $P'(0) < 0$ .

- We keep  $\sigma \geq 0$  unchanged, replace matrix  $\hat{G}$  by a positive definite diagonal matrix  $\hat{D}$  and resolve the resulting linear system. Moreover, we use the same diagonal matrix for the construction of the first-type preconditioner.

**Theorem 9.** Consider Algorithm PCG with preconditioner  $C$  applied to system  $K\bar{d} = \bar{b}$  (with  $\hat{G}$  replaced by  $\hat{D}$ ). Then this algorithm finds the exact solution in its first iteration and  $P'(0) < 0$  for any value  $\sigma \geq 0$ .

The use of restarts is computationally more efficient than the recomputation of  $\sigma \geq 0$ .

## Computation of the barrier parameter

Most implementations of interior-point methods choose the value  $\mu$  in such a way that

$$0 < \mu < s_I^T u_I / m_I$$

(or  $\mu = \lambda s_I^T u_I / m_I$ , where  $0 < \lambda < 1$ ). Computational experience indicates that the algorithm performs best when components  $s_i u_i$  approach zero at a uniform rate. The distance from uniformity can be measured by the ratio

$$\varrho = \frac{\min_{i \in I}(s_i u_i)}{s_I^T u_I / m_I}$$

(the centrality measure). Clearly,  $0 < \varrho \leq 1$  and  $\varrho = 1$  if and only if  $S_I U_I e = \mu e$ . The value  $\lambda$  is then computed by using  $\varrho$ . Usually heuristic formulas are used for this purpose. In our implementation, we have used the formula

$$\lambda = 0.1 \min \left( 0.05 \frac{1 - \varrho}{\varrho}, 2 \right)^3$$

proposed by Vanderbei and Shanno. We have also tested other possibilities, e.g., formulas given by Argaez, Tapia and Velasquez, but the above formula has shown to be best.

## Numerical experiments:

Interior-point method was tested by using three sets each containing 17 test problems with 1000 variables. The results are listed in three tables, where:

- M - method for step-length selection (F - the first step accepted, L - line search).
- S - strategy for step-length restriction.
- P - the preconditioner used (the first and the second classes with complete (+) or incomplete (-) Gill-Murray decomposition).
- NIT - the total number of iterations.
- NFV - the total number of function evaluations.
- NFG - the total number of gradient evaluations (NFG is much greater than NIT, since the second order derivatives are computed by using gradient differences)
- NCG - the total number of CG iterations.
- NRS - the total number of restarts.
- NFAIL - the number of failures for a given set (the number of problems which have not been solved).

<sup>2</sup>R.H Byrd, J. Nocedal, R.A.Waltz: Feasible Interior Methods Using Slacks for Nonlinear Optimization.

## Direction determination (trust-region approach):

Linearization - the Newton method (after elimination of inactive constraints). Only active slacks are considered in the trust-region subproblem. Primal-dual formulation is used.

$$\begin{bmatrix} \hat{G} & 0 & \hat{A}_I & A_E \\ 0 & \hat{S}_I^{-1} \hat{U}_I & I & 0 \\ \hat{A}_I^T & I & 0 & 0 \\ A_E^T & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta \hat{s}_I \\ \Delta \hat{u}_I \\ \Delta u_E \end{bmatrix} = - \begin{bmatrix} \hat{g} \\ \hat{g}_s \\ \hat{c}_I + \hat{s}_I \\ c_E \end{bmatrix},$$

where  $\hat{g}_s = \hat{u}_I - \mu \hat{S}_I^{-1} e$  and

$$\begin{aligned} \hat{G} &= G + \check{A}_I \check{S}_I^{-1} \check{U}_I \check{A}_I^T, \\ \hat{g} &= g + \check{A}_I \check{S}_I^{-1} \check{U}_I \check{c}_I + \mu \check{A}_I \check{S}_I^{-1} e, \end{aligned}$$

Scaling

$$\begin{bmatrix} \hat{G} & 0 & \hat{A}_I & A_E \\ 0 & I & \hat{D}_I & 0 \\ \hat{A}_I^T & \hat{D}_I & 0 & 0 \\ A_E^T & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta x \\ \hat{D}_I^{-1} \Delta \hat{s}_I \\ \Delta \hat{u}_I \\ \Delta u_E \end{bmatrix} = - \begin{bmatrix} \hat{g} \\ \hat{D}_I \hat{g}_s \\ \hat{c}_I + \hat{s}_I \\ c_E \end{bmatrix},$$

where  $\hat{D}_I = \sqrt{\hat{S}_I^{-1} \hat{U}_I}$ . Notation

$$\bar{G} = \begin{bmatrix} \hat{G} & 0 \\ 0 & I \end{bmatrix}, \quad \bar{g} = \begin{bmatrix} \hat{g} \\ \hat{D}_I \hat{g}_s \end{bmatrix}, \quad \Delta z = \begin{bmatrix} \Delta x \\ \hat{D}_I^{-1} \Delta \hat{s}_I \end{bmatrix}.$$

Trust region subproblem:

$$\frac{1}{2}(\Delta z)^T \bar{G} \Delta z + \bar{g} \Delta z \rightarrow \min,$$

$$\hat{A}^T \Delta z + \hat{c} = 0,$$

$$\|\Delta z\| \leq \Delta,$$

(with the additional constraint  $\hat{s}_I + \Delta \hat{s}_I > 0$ ), where

$$\hat{A} = \begin{bmatrix} \hat{A}_I & A_E \\ \hat{D}_I & 0 \end{bmatrix}, \quad \hat{c} = \begin{bmatrix} \hat{c}_I + \hat{s}_I \\ c_E \end{bmatrix}, \quad \Delta \hat{u} = \begin{bmatrix} \Delta \hat{u}_I \\ \Delta u_E \end{bmatrix}.$$

The Byrd-Omojokun approach:  $\Delta z = \Delta z_V + \Delta z_H$ .

Vertical subproblem:

$$\|\hat{A}^T \Delta z_V + \hat{c}\| \rightarrow \min,$$

$$\|\Delta z_V\| \leq \delta \Delta,$$

where  $0 < \delta < 1$ . Horizontal subproblem:

$$\frac{1}{2}(\Delta z_H)^T \bar{G} \Delta z_H + (\bar{g} + \bar{G} \Delta z_V)^T \Delta z_H \rightarrow \min,$$

$$\hat{A}^T \Delta z_H = 0,$$

$$\|\Delta z_H\|^2 + \|\Delta z_V\|^2 \leq \Delta^2.$$

The additional constraint  $\hat{s}_I + \Delta \hat{s}_I > 0$  has to be taken into account.

Vertical step:

$$\begin{aligned}\Delta z_V^C &= -\frac{\|\hat{A}\hat{c}\|}{\|\hat{A}^T \hat{A}\hat{c}\|} \hat{A}\hat{c}, \\ \Delta z_V^N &= -\hat{A}(\hat{A}^T \hat{A})^{-1} \hat{c}\end{aligned}$$

( $\Delta z_V^C$  - The Cauchy step,  $\Delta z_V^N$  - The Newton step).

The dog-leg method:

- If  $\|\Delta z_V^C\| \geq \delta\Delta$ , then  $\Delta z_V = \frac{\delta\Delta}{\|\Delta z_V^C\|} \Delta z_V^C$ .
- If  $\|\Delta z_V^N\| \leq \delta\Delta$ , then  $\Delta z_V = \Delta z_V^N$ .
- If  $\|\Delta z_V^C\| < \delta\Delta < \|\Delta z_V^N\|$ , then

$$\Delta z_V = \Delta z_V^C + \alpha(\Delta z_V^N - \Delta z_V^C)$$

where  $\alpha$  is chosen so that  $\|\Delta z_V\| = \delta\Delta$ .

The additional constraint  $\Delta \hat{s}_I \geq 0$  can imply an additional decrease of the step-length.

Horizontal step:

$$\hat{A}^T \Delta z_H = 0 \Rightarrow \Delta z_H = \hat{Z} \Delta z_Z,$$

where columns of  $\hat{Z}$  form a basis in the null-space of  $\hat{A}^T$ . Then

$$\frac{1}{2}(\Delta z_Z)^T \hat{Z}^T \bar{G} \hat{Z} \Delta z_Z + \bar{g}_H^T \hat{Z} \Delta z_H \rightarrow \min,$$

$$\|\hat{Z} \Delta z_Z\|^2 + \|\Delta z_V\|^2 \leq \Delta^2,$$

where  $\bar{g}_H = \bar{g} + \bar{G} \Delta z_V$ . This is an unconstrained trust region subproblem, which can be solved by the Steihaug-Toint CG method (preconditioned by  $\hat{Z}^T \hat{Z}$ ). The use of  $\Delta z_H = \hat{Z} \Delta z_Z$  (instead of  $\Delta z_Z$ ) leads to the multiplication by the matrix

$$\hat{Z}(\hat{Z}^T \hat{Z})^{-1} \hat{Z}^T = I - \hat{A}(\hat{A}^T \hat{A})^{-1} \hat{A}^T.$$

Thus matrix  $\hat{Z}$  need not be computed. Notice that the preconditioner

$$\hat{A}^T \hat{A} = \begin{bmatrix} \hat{A}_I^T \hat{A}_I + \hat{D}_I^2 & \hat{A}_I^T A_E \\ A_E^T \hat{A}_I & A_E^T A_E \end{bmatrix}$$

(where  $\hat{D}_I^2 = \hat{S}_I^{-1} \hat{U}_I$ ) is the same as that used in line-search methods (this is the reason for our choice of  $\hat{D}_I$ ). Solution of the horizontal subproblem gives  $\Delta \hat{u}$  as a by-product.

## Step-length restriction:

After determination  $\Delta\hat{s}_I$  and  $\Delta\hat{u}_I$  from the Byrd-Omojokun trust-region subproblem we set

$$\begin{aligned}\Delta\check{s}_I &= -(\check{c}_I + \check{A}_I^T \Delta x + \check{s}_I), \\ \Delta\check{u}_I &= \check{S}_I^{-1} \check{U}_I (\check{c}_I + \check{A}_I^T \Delta x) + \mu \check{S}_I^{-1} e.\end{aligned}$$

Since  $s_I^+ > 0$  and  $u_I^+ > 0$  have to hold, step-lengths for  $s_I$  and  $u_I$  have to be restricted. we use the bounds

$$\begin{aligned}\bar{\alpha}_s &= \gamma \min_{i \in I, \Delta s_i < 0} \left( -\frac{s_i}{\Delta s_i} \right), \\ \bar{\alpha}_u &= \gamma \min_{i \in I, \Delta u_i < 0} \left( -\frac{u_i}{\Delta u_i} \right),\end{aligned}$$

where  $0 < \gamma < 1$  and define  $x^+ = x + \Delta x$ ,  $s_I^+ = s_I(1)$ ,  $u_I^+ = u_I(1)$ ,  $u_E^+ = u_E + \Delta u_E$ , where

$$\begin{aligned}s_I(\alpha) &= s_I + \min(\alpha, \bar{\alpha}_s) \Delta s_I, \\ u_I(\alpha) &= u_I + \min(\alpha, \bar{\alpha}_u) \Delta u_I.\end{aligned}$$

Notice that the step-length for  $\hat{s}_I^+$  is usually restricted by using additional constraints in the Byrd-Omojokun trust-region subproblem.

## Merit function for trust-region reduction:

$$\begin{aligned} P(\alpha) &= f(x + \alpha\Delta x) - \mu e^T \ln(S_I(\alpha))e \\ &+ (u_I + \Delta u_I)^T (c_I(x + \alpha\Delta x) + s_I(\alpha)) \\ &+ (u_E + \Delta u_E)^T c_E(x + \alpha\Delta x) \\ &+ \frac{\sigma}{2} \|c_I(x + \alpha\Delta x) + s_I(\alpha)\|^2 \\ &+ \frac{\sigma}{2} \|c_E(x + \alpha\Delta x)\|^2, \end{aligned}$$

where  $\sigma \geq 0$ . Obviously,

$$P'(0) = (\Delta z)^T (\bar{g} + \hat{A}\Delta\hat{u} + \sigma\hat{A}\hat{c}).$$

**Theorem 10.** Denote by

$$Q(\alpha) = P(0) + \alpha P'(0) + \frac{\alpha^2}{2} (\Delta z)^T \bar{G} \Delta z$$

the quadratic approximation of  $P(\alpha)$ . Let  $\Delta z$  be the solution of the Byrd-Omojokun trust-region subproblem (with residual vector  $\hat{r} = \hat{A}^T \Delta z + \hat{c}$  such that  $\|\hat{r}\| < \|\hat{c}\|$ ) and let

$$\sigma > \frac{(\Delta z)^T (\bar{g} + \hat{A}\Delta\hat{u}) + \frac{1}{2} (\Delta z)^T \bar{G} \Delta z}{\hat{c}^T (\hat{c} - \hat{r})},$$

then  $Q(1) < Q(0)$ .

## Trust region strategy:

- We compute  $\Delta z$  by using the Byrd-Omojokun trust-region subproblem. Then either  $\|\Delta z\| = \Delta$  or the horizontal subproblem is solved with a sufficient precision.
- We set  $x^+ = x + \Delta x$ ,  $s_I^+ = s_I(1)$ ,  $u_I^+ = u_I(1)$ ,  $u_E^+ = u_E + \Delta u_E$  if  $P(1) < P(0)$  and  $x^+ = x$ ,  $s_I^+ = s_I$ ,  $u_I^+ = u_I$ ,  $u_E^+ = u_E$  otherwise.
- Denoting

$$\rho = \frac{P(1) - P(0)}{Q(1) - Q(0)},$$

we set

$$\begin{aligned}\Delta^+ &= \beta \|\Delta z\| & \text{if } \rho < \underline{\rho}, \\ \Delta^+ &= \Delta & \text{if } \underline{\rho} \leq \rho \leq \bar{\rho}, \\ \Delta^+ &= \gamma \Delta & \text{if } \bar{\rho} < \rho.\end{aligned}$$

Here  $0 < \beta < 1 < \gamma$  and  $0 < \underline{\rho} < \bar{\rho} < 1$ .
